## GEOLOGIC SUMMARY

### INTRODUCTION

The J. W. Dalton Test Well No. 1 is located in the NW 1/4 of protracted Section 14, T18N, R5W, Umiat Meridian, approximately 3 miles east of Camp Lonely and approximately 85 miles east-southeast of Barrow, Alaska. The location was situated adjacent to the Beaufort Sea Coast on Pitt Point (see Figures 1 and 2).

Drilling operations commenced on May 7, 1979. The well was plugged and abandoned and the rig released on August 1, 1979, after reaching a total depth of 9,367 feet below kelly bushing. Indications of residual hydrocarbons were noted in the Shublik and Ivishak Formations and the Lisburne Group. Five drill-stem tests were performed, and all indicated no commercial hydrocarbons were present. No other zones exhibited any significant hydrocarbon shows.

### Pre-Drilling Prognosis:

The primary objective of drilling the J. W. Dalton well was to test the sandstones and coarser clastics of the Ivishak Formation at a location that was structurally isolated from surrounding wells (W. T. Foran No. 1 and Drew Point No. 1). Secondary objectives were the basal "Pebble Shale" sandstones (Kuparuk Sandstone equivalent), Sag River Sandstone, and the Lisburne Group carbonates and clastics.

Structural closure at the Ivishak seismic horizon was dependent upon truncation by the basal Cretaceous unconformity. Trapping of hydrocarbons in the "Pebble Shale" sandstones was dependent upon stratigraphic pinchout of permeable sandstone. The interpreted trapping mechanism for the Lisburne carbonates was dependent upon truncation to the north of the location by the basal Cretaceous unconformity, onlap of the unit onto the Barrow High to the northwest, and upon regional dip to the south and east. Permeability in the Lisburne was principally expected in the dolomite.

Maturation studies indicated that both oil and gas could be expected throughout the lower Cretaceous and Triassic-Permian rocks.

### Post-Drilling Analysis:

The well was drilled to a total depth of 9367' into the argillite basement rocks of Indeterminate age. The top of the argillite was penetrated nearly 700 feet lower than forecast.

The primary objective, the Ivishak Formation, was penetrated almost 270 feet lower than forecast and was found to contain water-saturated porous clastics with varying amounts of residual asphaltic oil. Permeability of the Ivishak clastics reached a high of 756 millidarcies, with the best average permeabilities and porosities being developed in the upper part of the formation (see Appendix E).

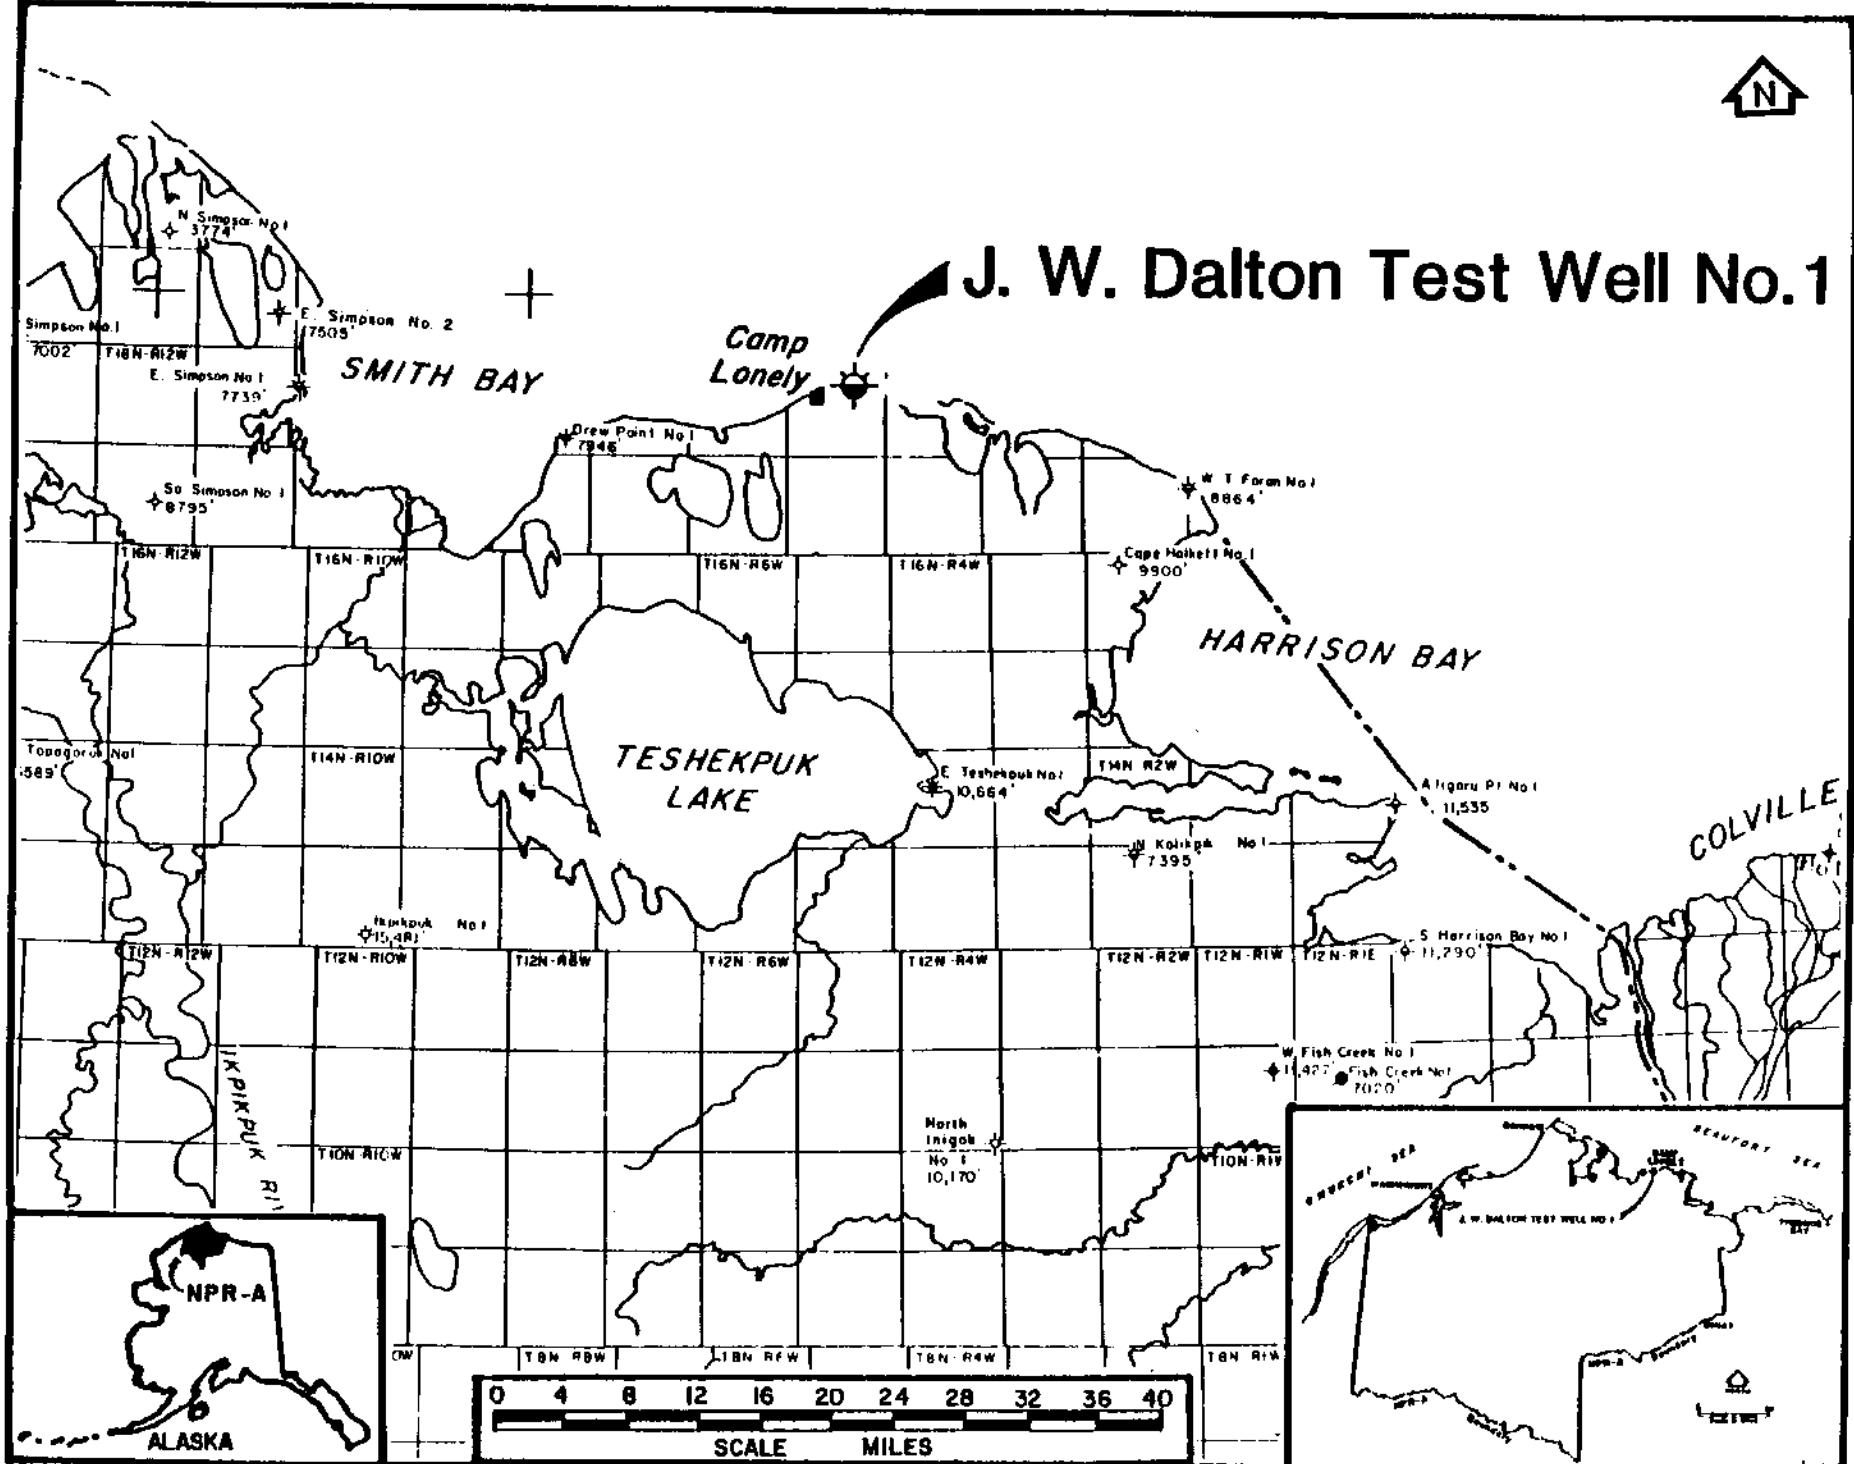

The "Pebble Shale" sandstones have low porosity and permeability in the well. A bed of tight silty sandstone, which exhibited traces of stain and dead oil, is present in the basal Torok Formation immediately above the "Pebble Shale".

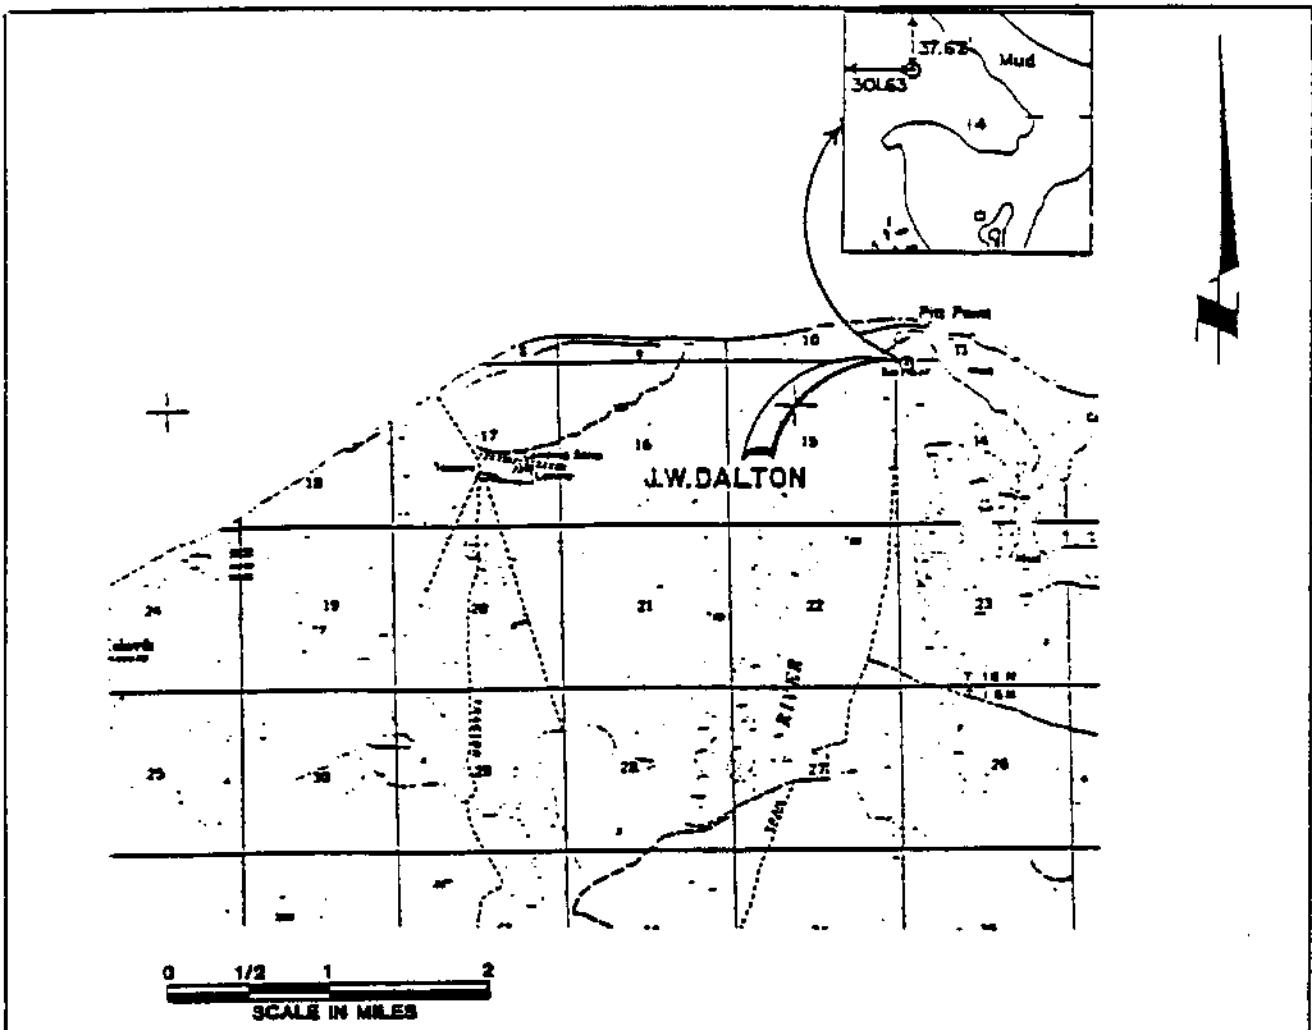

The Sag River Sandstone is not present in the well. The Lisburne Group carbonates were penetrated almost 500 feet lower than originally forecast. The Lisburne rocks did exhibit some porosity, but permeabilities averaged less than 1.0 millidarcies. The unit contained heavy residual asphaltic oil and water.

Five drill-stem tests were run in the Ivishak and Lisburne strata combined, two of which recovered minor amounts of asphaltic oil along with formation water and drilling fluids.

The drilling of the J. W. Dalton No. 1 well again confirmed the presence of potential reservoir rocks in the area within the Ivishak Formation. The presence of dead oil in the Ivishak and Lisburne implies hydrocarbons have been generated, but have since migrated through the area to some structurally higher position.

WELLSITE GEOLOGIST REPORT  
BY: R. V. NELSON  
EDITED BY: GORDON W. LEGG

## INTRODUCTION

The J. W. Dalton Test Well No. 1 was drilled in 1979 as a follow-up to the W. T. Foran Test Well No. 1, and the Drew Point Test Well No. 1. The W. T. Foran was drilled in 1977 by Husky Oil NPRA/U. S. Navy, and the Drew Point was drilled in 1978 by Husky Oil NPRA/USGS. The W. T. Foran, although not productive, had good shows of oil in the Kuparuk Sandstone equivalent and in the Ivishak Formation of the Sadlerochit Group. These two intervals flowed water to the surface on drill-stem tests, thus demonstrating the presence of excellent potential reservoirs should a prospect be developed which would prove to have stratigraphic/structural closure on either of the two sandstones.

The basic play was dependent on stratigraphic trapping in the Ivishak Formation through erosional truncation by the basal Cretaceous unconformity. A secondary objective, the Lisburne Group of carbonates, was dependent on porosity development through possible "dolomitization" coupled with stratigraphic closure created through erosional truncation to the north by the basal Cretaceous unconformity, onlap pinchout to the northwest (as indicated in Drew Point), and regional dip to the south and east. The Sag River Sandstone was believed to have been removed by erosion, which proved to be the case.

The Ivishak Formation was present, as expected, and was fairly well-developed and porous. The Ivishak consisted of clastics ranging from very fine grained sand to conglomerate, and contained spotty dead oil and asphalt throughout. Lisburne carbonates were also present and had some porosity; heavy oil staining and asphalt were noted throughout. A clastic sequence was encountered below the limestone and also contained dead oil. This clastic facies is equivalent to the Lower Lisburne. Five drill-stem tests were run, one open-hole in the Ivishak and four cased hole tests, three of which were in the Lisburne and the final cased hole test being again in the Ivishak. Both of the Ivishak tests flowed water to the surface (see Appendix F for complete drill-stem test data).

The J. W. Dalton Test Well No. 1 was completely evaluated by sample analysis, mud-logging data, conventional coring, and, finally, drill-stem testing. Fair shows, dead oil, and asphalt were noted and probably indicate flushing and lack of closure. It is possible that additional work, primarily seismic, could identify a prospect having the necessary closure, but the prospect would most likely be to the north off the National Petroleum Reserve.

## QUATERNARY-TERTIARY

94-210'

From the surface casing at 94' to a depth of 210', the samples consist of unconsolidated clay, sand, and gravel with layers of soft peaty wood and plant material. Foraminifera, as well as other shell fragments, are common. Electric logs confirm the interbedded nature of the sediments. Pyrite replacements are common in the plant material.

Foraminiferal studies, by Anderson, Warren & Associates, Inc. (AWA), suggest a Pliocene to Pleistocene age and a shallow, probably inner neritic, depositional environment. Palynological studies yielded no data useful in determining the age of these beds.

## TERTIARY

210-907'

Below 210' there is no marked change in the nature of the sediments. Thin organic layers persisted through the interval with a slightly increasing degree of carbonization. The sediments are unconsolidated,

with clay clasts common in fresh cuttings. These clay cuttings broke down with washing or just with time in wet samples, so that sample descriptions tend to be biased toward the coarser fractions. Small pebbles are common throughout the sands. From 769-910' a chert gravel with thin layers of wood was logged.

Though barren of foraminifera, palynology placed the interval from 270-900' into zonules P-M11 and P-M12 (Paleogene). A marine to marginal marine environment is suggested.

## CRETACEOUS

### Nanushuk Group (undifferentiated): 907-4714'

The Upper Cretaceous sediments, as picked on palynology, are those in the interval 900-2970', and are classified into AWA zonules P-M13-P-M16. Late Cretaceous foraminifera of AWA zones F-5 through F-8 occur between 1050' and 2820'. The section consists primarily of soft gray claystones with thin sand and silt beds. The depositional environment seems to have cycled from marginal marine to outer neritic, to open marine, and then back to marginal marine.

The claystones broke down easily and the hole "made mud" while drilling through the Nanushuk. Fine carbonaceous material and mica flakes are common throughout. Silt and sand layers are present in the claystone in what appears to be a gradational sequence. In the lower portion of this section a few thin, coarse grained, reddish stained, varicolored sands were logged.

While drilling the Nanushuk, the total background gas in the mud rose from traces near the top to 40 units near the base. (As used in this area, 100 units are equal to 2% methane mixed with air. Levels of 50-100 units are common in fast drilling and soft sediments in the area.) In this well the Lower Cretaceous is represented by the section from 2970-7650', based on palynology, and from 2820-7730', based on foraminifera. Foraminifera zones F-9 and F-10 (Albian) are represented, and a neritic environment is indicated. Palynology for the interval 2970-7380' indicated an age of Middle to late Albian AWA zonule P-M17 and suggested a marine environment. This portion of the Nanushuk consisted almost entirely of medium gray claystones, with only occasional sands and silts. Plant material, pyrite, mica, and shell fragments are common in the samples.

Core No. 1 was cut from 3500-3530' and recovered mostly soft claystone, which is dark gray and silty, with pelecypod fragments common. Interbedded with the claystone is a zone of dark gray argillaceous siltstone with occasional small rounded pebbles and lighter gray, fine grained sandstone clasts and flat-lying sand laminations. Core No. 2 from 4667-4697' showed a change to interbedded and interlaminated fine grained sandstone, alternating with a firm claystone, which showed the beginnings of shaly fissility. Sands showed multidirectional crossbedding.

Torok Formation: 4714-7483'

The Torok can be broken down to the soft shale from 4714-7380' and the hard siltstone, sandstone and shale from 7380-7483'. The upper shale portion yielded assemblages from the AWA palynology zones P-M17 and P-M18 (Middle and Upper Albian and Aptian to Early Aptian, respectively). Foraminifera from the interval 4740-7380' were classified into AWA zone F-11 (Aptian to Early Albian). Foraminifera types indicated open marine to possibly bathyal conditions. The section from 4740-7380' consists almost entirely of fine grained clastics grading from medium to dark gray claystone to medium dark gray and brown shale. Only occasional thin sands are present. Mica, pyrite and shell fragments are common. Portions of the shale are silty, grading to dark gray and brown siltstones. Occasional traces of siliceous, brittle, gray shale were seen in the samples. Core No. 3 was cut from 5603-5633' and recovered 27'. The core consists of thinly interlaminated soft shale and harder siliceous shaly bands each about 1" thick, with occasional zones of siltstone and sand up to a few inches thick. Core No. 4 was cut from 6585-6615' but recovered only 4.3'. The recovered core consists of dark gray to gray-brown, firm to hard, silty and sandy shale, with a 3" layer of fine to very fine grained sandstone showing complex crossbedding.

The basal portion of the Torok, from approximately 7380-7483', shows a marked change to hard, argillaceous siltstone and sandstone. Foraminifera from this interval yielded a Neocomian age (AWA zones F-12 - F-13), and suggested a probable middle to outer neritic environment.

"Pebble Shale": 7483-7755'

The "Pebble Shale" is distinctive both on logs and in samples. On electric logs the top is characterized by high gamma ray levels. Core No. 5 was cut from 7524-7534' and recovered 8.6'. The core is characteristic of the "Pebble Shale" and consists of finely laminated very dark gray or brown to black, hard, brittle shale. "Floating" throughout the shale are medium to coarse, well rounded, polished to frosted, quartz grains. Bedding planes have black, shiny carbonaceous material, which gave a very slow weak cut fluorescence, probably from asphaltic material. One thin, hard, pyritic siltstone layer about 2" thick was recovered in the middle of the core. Also seen in the core are fine pyrite laminations. The first lamination was encountered in the hard sandstone and siltstone just above the "Pebble Shale".

The Kuparuk Sandstone, or equivalent, is poorly developed at this location. It consists of thin, glauconitic, conglomeratic sandstones and siltstones interbedded with black shale. A slight increase in the background gas was noted through this zone, but did not constitute a show.

The base of the "Pebble Shale" was picked at 7755' from electric logs. Pre-Cretaceous erosion removed the Kingak Formation of Jurassic age and the Sag River Sandstone of Triassic age. The "Pebble Shale" rests unconformably on the Shublik Formation in the J. W. Dalton well.

## TRIASSIC

### Shublik Formation: 7755-7893'

The Shublik Formation consists of thin, hard, very calcareous sandstones which frequently grade to sandy limestones. Interbedded with the sandstones are hard calcareous siltstones and thin calcareous shales. Porosities in the sandstones are generally poor, estimated to be generally less than 5%. Occasionally, a slow, dull yellow cut fluorescence was obtained from selected sandstone cuttings through this interval.

No conventional cores were attempted in the Shublik because of a lack of either good shows or porous sandstones.

Foraminifera indicate a Middle to Late Triassic age (AWA zone F-19).

## TRIASSIC-PERMIAN

### Sadlerochit Group: 7893-8318'

The Sadlerochit Group is represented by rocks of the Ivishak Formation. Based on foraminiferal identification rocks of the underlying Echoak Formation are absent. The upper 340 feet of the Ivishak consists primarily of sandstone with some interbedded shales, and the lower 85 feet consists of shale belonging to the Kavik Shale Member.

Lithologically, the Ivishak is predominantly sandstone. The sandstones range from very fine grained (gradational to siltstone) to conglomeratic. The conglomerates contain mostly chert pebbles as the large fraction. The sandstones and conglomerates are interbedded with thin, relatively hard, gray to green, micaceous shales.

The Ivishak was continuously cored (Cores 6-10) from 7967-8200' (see Appendix E for core analysis). Slight scattered oil shows accompanied by slight to moderate gas shows (maximum of 150 units) were logged in the section from the top of the Ivishak to the first cored interval. The cores also contained spotty scattered oil staining as well as asphalt and dead oil. The spotted and scattered nature of the oil staining and the presence of asphalt and dead oil typically indicates a zone which has been "flushed" with water. Porosity and permeability in the cores are fair (see Appendix E).

An open-hole drill-stem test was run on the interval from 7812-8140' (Test No. 1). The test flowed water with small amounts of solution gas at the rate of 1,218 barrels per day on a 1/4" choke. The flowing surface pressure reached a maximum of 300 psi according to the drill-stem test report from the field. The formation was retested (Test No. 5) through casing (perfs 7971-7976'). This test flowed water at the rate of 258 barrels per day at a stabilized surface pressure of 110 psi as reported from the field (see Appendices F & G).

The Kavik Shale Member of the Ivishak Formation is represented by a gray, partly splintery, micaceous shale having thin silty beds. The depositional environment for the Kavik is interpreted as being nonmarine to marginal marine.

#### PENNSYLVANIAN-MISSISSIPPIAN

##### Lisburne Group: 8318-9270'

Only the upper part of the Lisburne carbonates appears to be present in this well. This upper limestone unit is interpreted as being deposited in a shoaling shelf and subtidal to tidal type environment. The interval 8318-9160' has been dated as Early to Middle Pennsylvanian. The foraminifera report from Anderson, Warren and Associates, Inc. states that the absence of the lower carbonate unit can be due either to an unconformity between the Lisburne Group and the underlying Endicott Group or to a facies change in the lower Lisburne. The facies change may have allowed clastics normally associated with the Endicott Group to have climbed in the section with respect to age. A possible Mississippian age was assigned to the clastic section from 9160-9270'.

Two conventional cores were cut, No. 11 from 8315-8345', and No. 12 from 8515-8543.5'. Cores and samples consist of finely to coarsely crystalline limestone that is medium to dark gray and brown. Porosity is generally low, and consists primarily of pinpoint vug porosity and fractures. The limestones throughout showed dead and heavy asphaltic oil staining, which was occasionally bleeding from fractures and pinpoint pores. Chert pebbles and occasional chert conglomerates were also logged, including one such conglomerate one-inch thick which was recovered at the top of Core No. 11. Traces of dead oil also were noted in drill cuttings. Interbedded with the limestones of Core No. 12 are calcareous sandstones which are brown, fine to medium grained, angular and containing dead oil stain and bleeding heavy black asphaltic oil. Some red and green claystones were present in the bottom 7.1' of the recovery from Core No. 12.

Two drill-stem tests were run in the Lisburne carbonates. Drill-Stem Test No. 3 through perforations in the intervals 8482-8509' and 8520-8538' recovered 22 barrels of oil-cut water and 5 barrels of water-cut heavy oil. Drill-Stem Test No. 4 through perforations in the interval 8392-8436' died after 28 minutes into the initial flow and recovered only water cushion, which was slightly mud cut, and an estimated 1.3 barrels of mud. Both the water cushion and the mud had a slight sheen of oil (see Appendix F for complete drill-stem test data).

The lower portion of the Pennsylvanian section in this well is represented by clastics consisting of red and green shales interbedded with green to red and varicolored sandstones, mostly very fine grained with some medium grained, silty and very calcareous, exhibiting mostly poor porosity. The sandstones become conglomeratic in the lower part, containing pebbles of chert. Scattered sandy limestones were also logged. The Pennsylvanian was picked as low as 9160', but below that point dating breaks down. The

rocks could be as old as Early Mississippian or as young as Early Pennsylvanian. The depositional environment was probably nonmarine to marginal marine.

One drill-stem test (Drill-Stem Test No. 2) was run in red clastics through perforations over the interval 8558-8665'. This test recovered 80 barrels of formation water and 5 barrels of asphalt when reversed out (see Appendix F for details).

#### INDETERMINATE

##### Argillite: 9270-9367'

Rocks of Indeterminate age, collectively called argillite in most areas of the North Slope, were encountered at a depth of 9270'. The lithology consists of dark gray to black, slickensided, quartz-veined shales, which have been subjected to low-grade metamorphism. The so-called argillite is considered to be economic basement throughout the area.

#### STRUCTURE

Two runs were made with a 4-arm dipmeter tool from 2600' to total depth. Computed dips appear to be close to those seen in the cores.

From 2600' down to the top of the "Pebble Shale" computed dips are quite gentle with most being less than 5° and often nearly flat. The direction of dip varied, but was generally northeast to southeast.

From the "Pebble Shale" to total depth the dips increased slightly, but still held generally under 10°. The dip direction was very consistent to the southeast and did not show any marked changes in the lower section that might indicate an unconformity.

The presence of potential reservoir rocks in the lower part of this well and the general southerly dips would indicate that a trap could still exist updip from this well. Unfortunately, any likely play would exist north of the J. W. Dalton location and would, therefore, be situated off of the National Petroleum Reserve.

Hydrocarbon Shows:

- 7878-7921' Shublik and Ivishak Formations: sandstone; trace light brown spotted oil stain, trace yellow cut fluorescence, maximum ditch gas @ 7884', 150 units.
- 7955-8887' Sadlerochit and Lisburne Groups: sandstone, conglomerate, and limestone; scattered residual heavy oil show throughout, in part asphaltic; entire section water wet with occasional to common spotted black asphaltic stain, occasional gold speckled fluorescence common, dull to bright yellow cut fluorescence; better shows associated with tighter rocks.

Core Analysis:

Date	Interval	Core No.	Sample No.
7-6-79	7967-8011'	6	1 thru 37
	8029-8081'	7	38 thru 70
	8081-8090'	8	70 thru 76
	8114-8139'	9	77 thru 101
	8140-8198'	10	102 thru 160
	8317-8341'	11	161 thru 173
	8515-8536'	12	174 thru 195

Tests:

Drill-Stem Test No. 1, 7812-8140': Sadlerochit (open hole), recovered fresh water then salt water. Flowed at rate of 1,218 BWPD.

Drill-Stem Test No. 2, 8558-8665': Lisburne (perforations), recovered 3.31 barrels of water cushion, 5 barrels of asphalt, 2 barrels of rat-hole mud, and 29 barrels of rat-hole fluid and mud filtrate plus 80 barrels of formation water.

Drill-Stem Test No. 3, 8482-8509' and 8520-8538': Lisburne (perforations), recovered 6.8 barrels of water cushion and rat-hole mud, 5 barrels of oil, and 22 barrels of formation water.

Drill-Stem Test No. 4, 8392-8436': Lisburne (perforations), no hydrocarbon recovery. Recovered water cushion and 1.3 barrels of mud with a sheen of oil.

Drill-Stem Test No. 5, 7971-7976': Sadlerochit (perforations), recovered 3.3 barrels of water cushion, 162 barrels of formation water. Flowed water at rate of 258 BWPD.

DEPTH DRILLED  
(FEET BELOW  
KELLY BUSHING)

0 - 94	No samples.
94 - 130	Clay: medium to light gray, soft, gummy, trace amounts of fine to medium grained sand, occasional pelecypod fragments and forams.
130 - 150	Peat: soft wood and plant material, partially pyritized and carbonized; small amounts of pyritic coal, with sand and fine gravel; pelecypod fragments common; well preserved forams were noted.
150 - 240	Sand/Gravel: varicolored, mostly orange with yellows, reds, greens, blues and grays; poorly sorted, coarse fractions rounded to subrounded, with surface textures from frosted to polished; sands subangular to rounded, some clear, very well rounded quartz, and with thin beds of soft, medium gray clay; occasional thin layers of peat and wood organic material; traces of shell fragments and pyrite.
240 - 310	Chert Pebble Conglomerate: dark gray, poorly sorted, subrounded to well rounded, mixture of frosted and well polished granules and pebbles; many pebbles show remains of pyrite on surfaces as well as traces of calcareous cement.
310 - 480	Clay: medium gray, soft, silty; carbonaceous and sandy in part; interbedded with dark gray chert pebble conglomerate, as above.
480 - 590	Sand: more finer sizes and fewer pebbles and granules; angular to subangular in sand sizes; predominantly quartz and chert, with clay and organic layers, as above.
590 - 780	Gravel: sandy at top; mostly dark gray and medium gray chert, upper portion has 5-10% varicolored rock fragments; moderately to well size graded, some small pebbles; rounded to subrounded, many well polished; some wood as thin, carbonized zones at 610'.

780 - 920	Gravel: dark gray chert pebbles, rounded to subrounded, many polished grains; some broken fragments of larger pebbles; occasional zones of carbonized wood material.
920 - 1075	Gravel: dark gray chert pebbles, and many broken fragments of larger chert pebbles.
1075 - 1290	Clay: medium gray, soft, plastic, slightly silty; occasional fine carbonaceous particles.
1290 - 1450	Clay: medium to light gray, soft to firm, silty; grading occasionally to argillaceous Siltstone: medium gray, soft, sandy; traces of pelecypod shell fragments; very fine carbonaceous grains and mica flakes in both clay and silt.
1450 - 1650	Sand: medium gray, very fine grained, silty and clayey; mostly quartz, but with trace amounts of bright, varicolored grains, which are probably very thinly interbedded in siltstones and clays.
1650 - 1750	Clay: as above; thinly interbedded with Sandstone: as above.
1750 - 1920	Siltstone, Clay and Claystone: as above.
1920 - 1930	Sand: coarse grained, well rounded, numerous clear quartz grains; some very fine grained, firm, gray sandstone.
1930 - 2010	Claystone and Clay: as above.
2010 - 2120	Clay: medium and light gray; becoming progressively more firm and grading to soft, plastic claystone, with light gray patches of bentonite?; silt content varies greatly; mica and fine carbonaceous material are common; traces of pelecypod shells and plant stems.
2120 - 2290	Claystone: medium to light gray, plastic; occasional slight fissility.
2290 - 2370	Claystone: medium gray, soft, less silty; mica common.
2370 - 2410	Siltstone: medium gray, argillaceous, micaceous, calcareous, firm to occasionally hard, with Claystone: as above.
2410 - 2500	Sand: red stained, coarse grained; mostly quartz; very well rounded; often clear or polished, with Siltstone and Claystone: as above.

- 2500 - 2530      Claystone: medium to light gray, soft, silty, grading to siltstone, micaceous, and with Siltstone: as above.
- 2530 - 2690      Siltstone: light gray with scattered dark grains, argillaceous, micaceous, calcareous, pyritic, with Claystone: as above.
- 2690 - 2800      Siltstone: medium gray, argillaceous, slightly calcareous to occasionally hard; abundant fine mica; minor amount of carbonaceous material; sandy, with occasional hard, calcareous, very fine grained sandstone and coarse grains of loose sand; interbedded with, and grading to, soft, medium gray, silty claystone; traces of gray to brown, crystalline calcite; pyrite clusters common.
- 2800 - 2950      Claystone: medium to dark gray, soft, silty, slightly carbonaceous; scattered fine mica; occasional light gray, firm, bentonitic clay.
- 2950 - 3070      Claystone: medium to dark gray, soft to firm, silty, carbonaceous.
- 3070 - 3220      Claystone: medium to dark gray, firm, slightly silty, carbonaceous, micaceous, pyritic; trace of amber; Sandstone: very fine grained, hard, calcareous; probably as very thin beds.
- 3220 - 3360      Claystone: medium to dark gray, soft to firm, only occasionally silty, and with thin, argillaceous siltstone interbedding; traces of chert and shell fragments.
- 3360 - 3500      Claystone: medium to dark gray, soft to firm, pyritic, occasional thin, soft, argillaceous, calcareous, gray siltstone; pyrite clusters; worm tubes and pelecypod shell fragments common.
- 3500 - 3530      Core No. 1: Cut 30', Recovered 27'
- 3500.0-3503.0'    No recovery.  
(3.0')
- 3503.0-3508.0'    (5.0')      Siltstone: dark gray, argillaceous, grading to silty claystone; firm, occasional small rounded pebbles throughout; lighter gray, hard, very fine grained sandstone in casts and relatively flat-lying laminations.
- 3508.0-3530.0'    (22.0')     Claystone: dark gray, firm to soft, slightly silty, but less than above; no evidence of fissility, generally

		undercompacted; pelecypod shells (1-10 cm) and other shell fragments common; some thin-shelled types; prismatic shell layers often recrystallized to clear, amber colored crystalline calcite.
3530 - 3600	Siltstone: dark gray, argillaceous, sandy, with hard, fine grained sandstone clasts and laminations, with Claystone: dark gray, soft to firm, pelecypod shells common.	
3600 - 3810	Claystone: medium to dark gray, soft to firm, silty, with Siltstone: medium to dark gray, soft, argillaceous, calcareous, carbonaceous, with occasional Sandstone: dark green, very fine grained, hard, calcareous; traces of Limestone: dark gray, hard, argillaceous, crystalline.	
3810 - 3940	Claystone: medium gray, soft, micaceous; pelecypod shells and carbonized plant fragments common.	
3940 - 4070	Claystone: medium gray, soft, slightly silty; minor Siltstone: dark gray, hard, calcareous; scattered small rounded pebbles; occasional carbonized wood.	
4070 - 4240	Claystone: medium gray, soft, micaceous; scattered pebbles; occasional loose grains of coarse sand; trace of dark gray, finely crystalline, argillaceous limestone, containing abundant plant remains.	
4240 - 4370	Claystone: medium gray, soft to firm, soluble, silty, carbonaceous, micaceous; pyrite, pelecypod shells and soft plant remains common.	
4370 - 4470	Claystone: medium to dark gray, soft, silty, carbonaceous, micaceous; abundant shell fragments, many of which are weathered to a chalky texture.	
4470 - 4600	Claystone: medium gray, soft to firm, silty, carbonaceous, micaceous; traces of coal, pyrite and shell fragments; abundant white, red, and brown weathered clayey material below 4530'.	
4600 - 4667	Claystone: as above, with occasional chert and quartz pebbles and granules; minor very fine grained sand.	
4667 - 4697	<u>Core No. 2: Cut 30', Recovered 30'</u>	
4667.0-4670.5' (3.5')	Claystone/Shale: finely laminated, dark gray to brown, firm, silty; Siltstone: dark gray to brown, argillaceous, and showing low angle crossbedding.	

- 4670.5-4675.0' (4.5') Claystone/Shale: dark gray to dark brown in 2-25 mm thick laminations with 0.5-2 mm thick silt and sand laminations showing soft sediment distortion; interlayered with 2-10 mm thick sandy Siltstone: argillaceous, micaceous; and 5-10 mm thick sands, very fine grained, medium gray, soft to firm, noncalcareous, with dark carbonaceous streaks; mica and clay clasts; shows very multi-directional crossbedding, some small sand casts.
- 4675.0-4679.3' (4.3') Claystone/Shale: dark gray to gray-brown, firm, clean to silty with 1-3 mm silt laminations, and 15-30 mm irregular sands showing internal crossbedding at 4675.9' and 4677.2'.
- 4679.3-4681.3' (2.0') Sandstone: very fine grained, medium to light gray with black streaks of carbonaceous material, micaceous, argillaceous, with 1-10 mm silty shale laminations making up about 20%; some low angle crossbedding in sand and some small lenses of siltstone; interval is uniform in appearance.
- 4681.3-4683.7' (2.4') Claystone/Shale: dark gray to gray-brown, firm, clean to silty, occurs as 2-15 mm interlaminations with 1-5 mm thick, fine grained sand; approximately 50% each; regularly laminated with occasional 2-4 mm thick, light gray silt and sand lenses.
- 4683.7-4685.7' (2.0') Sandstone: (approximately 60%) medium gray, very fine to fine grained; in 1-5 mm laminations with Claystone/Shale (40%): dark gray, firm, shows fine, fairly regular cross-bedding with fluting at the base of sandier portions.
- 4685.7-4686.9' (1.2') Claystone: dark gray, firm, with occasional thin (1-4 mm) sand laminations.
- 4686.9-4688.0' (1.1') Sandstone: medium gray, very fine grained, firm, argillaceous, moderately carbonaceous, micaceous; with 2-4 mm shale laminations; some internal crossbedding and flute casting.

4688.0-4688.4' (0.4')	5-10 mm shale and 1-5 mm sand laminations showing soft sediment folding.
4688.4-4689.0' (0.6')	Sandstone: light gray, fine to very fine grained, hard, calcareous, with carbonaceous partings 0.5-1 mm thick.
4689.0-4689.8' (0.8')	Sandstone: medium gray, fine grained, slightly argillaceous, firm, with carbonaceous layers 0.5-4 mm thick.
4689.8-4690.9' (1.1')	Thin laminations (1-5 mm) of medium gray sandstone and dark gray shale, regularly layered.
4690.9-4693.2' (2.3')	Sandstone: medium gray, slightly argillaceous; fairly uniform, with 1-3 mm carbonaceous layers approximately 20 mm apart, noncalcareous, very fine to fine grained.
4693.2-4693.8' (0.6')	Evenly laminated 3-10 mm sandstone and 13 mm shale layers.
4693.8-4694.8' (1.0')	Shale/Claystone: dark gray with 10% sandstone in 1-2 mm laminations; dip appears less than 10°.
4694.8-4695.5' (0.7')	Approximately 50/50 1-10 mm laminations of medium gray sandstone and dark gray Shale: firm, micaceous, carbonaceous; soft sediment slump and fold convoluted bedding and lensing.
4695.5-4696.5' (1.0')	Sandstone: fine to occasionally medium grained, carbonaceous, with 15% shale in 1-5 mm laminations; uniform.
4696.5-4697.0' (0.5')	Shale/Claystone: dark gray, firm, clean.
4697 - 4830	Claystone/Shale: medium to dark gray, soft to firm, occasionally silty, with thin Sandstone: very fine grained, soft to hard, some loose grains, rounded to subrounded, fine to coarse grained sand.
4830 - 5040	Siltstone: medium gray to brown, argillaceous, carbonaceous, micaceous, sandy; and Shale: dark gray to brown, soft to firm, occasionally hard and siliceous; traces of light brown, hard, siliceous claystone; traces of blue chert, pyrite, pelecypod shells.

- 5040 - 5190 Claystone/Shale: medium to dark gray, generally firm, but ranging from soft and soluble to siliceous and hard; pyritic; traces of forams; occasional sand grains.
- 5190 - 5310 Siltstone: medium to light gray and brown, firm to hard, sandy, carbonaceous, micaceous, occasionally siliceous, argillaceous; with Shale: as above and with loose grains of coarse, rounded, varicolored sand; small columnar echinoid fragments, worm tubes and pelecypods.
- 5310 - 5603 Shale: medium to dark gray, firm to hard, occasionally silty; occasional pyrite.
- 5603 - 5633 Core No. 3: Cut 30', Recovered 27'
- 5603.0-5630.0' (27.0') Entire core consisted of rhythmically bedded shale and siltstone; color shows distinct steps from black to dark gray, to dark brown to gray, to light gray to light brown; darkest layers 1-3 mm thick; lightest gray sandy silt layers are 0.1 to 1 mm; core washed out in regular alternations of relatively hard and soft layers approximately 20 mm thick, so that the surface showed pronounced relief; harder layers medium brown and gray, silty, siliceous shale; softer parts are black to brown shale with very fine laminations of lighter gray silt and occasional very fine grained sand; occasional sandy zones up to 50 mm occur, such as at 5605'; a 30 mm layer of siliceous and possibly dolomitic, hard claystone was cored at 5612.5'.
- 5630.0-5633.0' No recovery.  
(3.0')
- 5633 - 5700 Siltstone and Shale. Siltstone: medium gray, carbonaceous, argillaceous, micaceous, occasionally clean and friable; Shale: medium to dark gray and brown, some well developed shaly partings, firm to hard, but still probably a significant percentage dissolving into the mud; traces of light brown, hard, siliceous shale.
- 5700 - 6090 Shale: dark gray, firm, carbonaceous, micaceous, occasionally silty, grading to argillaceous siltstone; occasional large, well rounded, clear quartz grains; trace of blue chert.

- 6090 - 6480      Shale: as above, with Siltstone: medium to light gray, grading to Sandstone: micaceous and dark brown, argillaceous, pyritic; occasional forams.
- 6480 - 6585      Shale: dark gray, firm to hard, occasionally silty, with Siltstone: medium to light gray, argillaceous, carbonaceous, sandy, micaceous, and with occasional Sandstone: very fine grained, medium to light gray, argillaceous and silty.
- 6585 - 6615      Core No. 4: Cut 30', Recovered 4.3'
- 6585.0-6588.4'    Shale: dark gray to gray brown, (3.4') firm to hard, silty and sandy, with Sand: light gray, very fine grained, siliceous, hard; laminations 0.5-5 mm thick and making up to 10% of interval; thicker sand layers show micro crossbedding and lensing.
- 6588.4-6588.7'    Sandstone: medium to light gray, fine (0.3') to very fine grained, grading finer downward; shows complex crossbedding; poor porosity.
- 6588.7-6589.3'    Shale: dark gray to brown, with a (0.6') 10 mm band of very fine grained sandstone.
- 6589.3-6615.0'    No recovery. (25.7')
- 6615 - 6750      Shale: dark brown, firm, silty; dark gray, clean, firm to occasionally hard in more siliceous portions; 30% Siltstone: medium to dark gray, with black "peppery" grains, argillaceous, carbonaceous, sandy, firm to hard; 5% Sandstone: very fine to fine grained, medium to light gray, salt and pepper, occasionally micaceous, calcareous, friable to hard.
- 6750 - 7150      Shale: getting progressively harder and cleaner downward; bladed in part, dark gray and gray-brown with the gray-brown being slightly more silty; in part platy; first traces of Inoceramus fragments; occasional traces of fine grained sand; traces of dark gray chert.
- 7150 - 7290      Shale: dark gray and brown, as above, with thin laminations of very fine to fine grained, hard, calcareous, carbonaceous sandstone and 10% fine grained, salt and pepper, gray friable sandstone; occasional larger loose grains, 25% Siltstone: ranging from dark

- gray, argillaceous and hard, to light gray and friable grading to sandstone; fine pyrite laminations; traces of inoceramus, chert grains and pebbles; glauconite filled forams; some papery shale fragments.
- 7290 - 7440      Shale with Sandstone and Siltstone: as above, with small amounts of dark gray-brown, hard lime mudstone; pyrite clusters common; chert pebbles; green rock fragments.
- 7440 - 7490      Sandstone: very fine grained, hard, light salt and pepper gray, occasionally friable with possibly fair porosity, micaceous, silty, grading to siltstone; fine pyrite streaks; minor Shale: dark silvery-gray, siliceous, hard, brittle; trace of red, dark gray and white chert.
- 7490 - 7524      Shale: very dark gray to black, carbonaceous, hard, siliceous, with medium to coarse grained, well rounded, clear quartz grains "floating" in the shale; with siltstone, sandstone and lighter colored shales probably still coming from above.
- 7524 - 7534      Core No. 5: Cut 10', Recovered 8.6'
- 7524.0-7532.6'    (8.6')      Shale: very dark gray and brown, hard, brittle, very finely laminated (less than 0.5 mm), black, shiny, carbonaceous material, which gives a very weak slow cut fluorescence, is common on bedding planes; very fine mica common, well rounded medium to coarse grained, frosted to polished, clear quartz grains are "floating" throughout the shale; pyrite occurs in seams less than 1 mm thick; Siltstone (approximately 50 mm thick): medium to dark gray, highly compacted, hard, pyritic, showing irregular beds or lenses at 7524.4' and 7528.3'.
- 7532.6-7534.0'    (1.4')      No recovery.
- 7534 - 7620      Shale: dark gray to black, slightly micaceous, rare floating sand grains; trace of pyrite; rare, very coarse grained sand grains.
- 7620 - 7623      Sandstone: gray to brown, slightly conglomeratic quartz, chert grains and pebbles; white to blue-gray opaque, siliceous; rare glauconite; oil staining, with yellow cut fluorescence.

- 7623 - 7715 Interbedded Siltstone: brown, gray, green-gray, partly friable, calcareous, sandy, glauconitic, with Sandstone: gray, gray-brown, silty, calcareous, subangular, well sorted, glauconitic; spotted stain, no odor, no fluorescence, yellow cut fluorescence; sandstone approximately 10% of cuttings; interbedded Shale: dark gray, black, micromicaceous, splintery.
- 7715 - 7777 Shale: very dark gray to black, with brown cast, trace brown streak, trace of floating, rounded sand grains, partly splintery; trace of Siderite: chocolate brown, dense, with rare, very finely disseminated pyrite; shell fragment, amber to resinous at 7749-7754'; at 7744' trace of interbedded Sandstone: brown, green, very fine grained, subangular, well sorted, silty, calcareous, glauconitic, sideritic, tight, and Siltstone: light gray, rare, scattered black grains, part very finely sandy.
- 7777 - 7810 Shale: very dark gray to black, trace of brown; interbedded Siltstone: light gray, trace of brown, calcareous; trace of Limestone: white, light gray, silty, sandy at 7781-7783'.
- 7810 - 7830 Sandstone: light gray, light brown, very fine grained, angular to subangular, well sorted, silty, calcareous to very calcareous, with shell fragments; grading to Limestone: brown, mottled, very sandy, shell fragments, slight dull yellow cut fluorescence.
- 7830 - 7878 Interbedded Siltstone: medium gray-brown, tight, calcareous; Shale: medium brown, very calcareous, silty; trace of Sandstone: light gray to brown, very fine grained, silty, calcareous; trace of shell fragments.
- 7878 - 7921 Sandstone: brown-gray, very fine grained, subangular, well sorted, friable, fair porosity; trace of glauconite; stained; trace of fine grained, friable; grades from no fluorescence to yellow cut fluorescence.
- 7921 - 7928 Shale: dark gray, splintery, trace of brown silty shale.
- 7928 - 7955 Shale: clayey, red, pink, cream, trace of mottled; interbedded Sandstone: white, very fine grained, siliceous, angular, well sorted, noncalcareous.
- 7955 - 7967 Sandstone: light gray, spotted oil staining, fine grained, angular, subangular, well sorted, gold fluorescence, slightly siliceous, slightly friable to friable, moderate porosity, scattered dead oil, trace of interstitial white clay, good streaming yellow cut fluorescence; bottom 4' white to very light gray, medium grained, friable, trace of loose grains, good porosity.

Core No. 6: Cut 54', Recovered 54'

- 7967.0-7970.0' (3.0') Sandstone: brown-gray, fine grained, angular, subangular, well sorted, rare white siliceous cement, clayey, trace of white grains; trace of orange grains; medium porosity, oil stained, gold sample fluorescence, bright yellow cut fluorescence.
- 7970.0-7979.0' (9.0') Sandstone: gray, very fine grained, silty, slightly argillaceous, with white clay; trace of chert pebbles; spotted stain, no sample fluorescence except at 7974' and 7978', which is gold and has bright yellow cut fluorescence.
- 7979.0-7983.0' (4.0') Sandstone: black, medium gray to brown, light gray, fine to medium grained, subangular, medium sorted, slight dead oil stain, spotted brown oil stain, faint gold sample fluorescence at 7979', bright yellow cut fluorescence, trace of Shale: medium gray, micaceous; trace of thin coal, with pyrite lense, at 7980'.
- 7983.0-7986.0' (3.0') Sandstone: light gray to gray, conglomeratic, with metamorphic and chert pebbles; Shale lense: medium gray; spotted oil stain in sandstone, no sample fluorescence except at 7984'; bright yellow cut fluorescence, slightly porous.
- 7986.0-7997.0' (11.0') Sandstone: gray, black-brown, fine to medium grained, subangular, medium sorted, friable, porous, dead oil stain, spotted oil stain; becoming heavy and asphaltic at 7988'; scattered pebbles; trace of siliceous streaks; streak with disseminated pyrite; chert grains common.
- 7997.0-8003.0' (6.0') Shale: medium gray, gray to green, micaceous, with Siltstone lenses: light gray, siliceous; trace of Sandstone: mottled gray to brown, orange, and light gray.
- 8003.0-8011.0' (8.0') Sandstone: mottled white and black, tripolitic chert grains and pebbles, fine

		grained, subangular, well sorted, spotted oil stain, dead oil stain; with Shale: gray-green, micaceous, siltstone lenses, siliceous.
8021 - 8081	8011.0-8021.0' (10.0')	Interbedded Shale, Siltstone and Sandstone: green, light green, finely micaceous, siliceous.
	<u>Core No. 7, Cut 60', Recovered 55'</u>	
	8021.0-8030.0' (9.0')	Siltstone: red, green, very light gray, slightly micaceous, argillaceous, rare sandstone streaks, rare green shale streaks.
	8030.0-8039.0' (9.0')	Sandstone: gray to brown, green, very fine to fine grained, angular, subangular, well sorted, poor oil stain; rare silty and sandy streaks, very faint gold sample fluorescence, bright yellow cut fluorescence.
	8039.0-8047.0' (8.0')	Siltstone: dark gray, dark gray to brown-green, finely micaceous, trace of Shale: red, micaceous, conchoidal fracture, rare siltstone streaks, with dead oil stain.
	8047.0-8050.0' (3.0')	Sandstone: gray, abundant black dead oil stain, very fine to fine grained, well sorted, rare pebbles and coarse white chert grains, faint gold sample fluorescence, bright yellow cut fluorescence.
	8050.0-8056.0' (6.0')	Shale: green, red, dark gray, micaceous; trace of silt and sand grains.
	8056.0-8058.0' (2.0')	Sandstone: gray, light gray to brown, very fine grained, subangular, well sorted, poor oil stain; becoming silty.
	8058.0-8060.0' (2.0')	Shale: green, micaceous, with silty and sandy streaks, trace of dead oil stain.
	8060.0-8064.0' (4.0')	Sandstone: black, brown, trace of white, mottled, fine grained, subangular, well sorted, heavy oil stain, dead stain, rare pebbles, trace of

		asphaltic oil, very faint gold sample fluorescence, bright yellow cut fluorescence; Siltstone: medium gray, slightly micaceous from 8061-8062'.
8064.0-8065.0' (1.0')	Shale:	green, finely micaceous, conchoidal fracture.
8065.0-8076.0' (11.0')	Sandstone:	conglomeratic, gray to brown chert grains and pebbles, white to gray, subangular to subrounded, poorly sorted, brown oil stain, very faint gold sample fluorescence, bright yellow cut fluorescence, trace of siliceous cement, trace of pebbles 1/2" to 1 1/2"; trace of quartzite pebbles; bottom part bleeding heavy oil, good porosity 8068-8071'; trace of Shale and Siltstone: green, orange; micaceous at 8072-8073'.
8076.0-8081.0' (5.0')	No recovery.	
8081 - 8113	<u>Core No. 8, Cut 32', Recovered 13.5'</u>	
8081.0-8081.5' (0.5')	Shale:	very dark gray, very fine to finely micaceous, conchoidal fracture, trace of fish remains.
8081.5-8094.5' (13.0')	Chert conglomerate:	pebbles of white to medium gray, subangular to subrounded, poorly sorted; Sandstone matrix: medium to very coarse grained, spotted heavy oil stain with asphaltic oil, no sample fluorescence, bright yellow cut fluorescence; pebbles in various sizes up to 2", many with slightly rounded shape, but essentially angular; quartzite pebbles common; slight to medium porosity, locally siliceous cement.
8094.5-8113.0' (18.5')	No recovery.	
8113 - 8139.5	<u>Core No. 9, Cut 26.5', Recovered 26.5'</u>	
8113.0-8122.0' (9.0')	Sandstone:	conglomeratic, light gray to gray, brown chert grains and white to gray pebbles, trace of quartzite

	pebbles, subangular to subrounded; Sandstone: fine to very coarse grained, angular to subangular, poorly sorted, slight to medium porosity, horizontal bedding with crossbedding approximately 20°; no sample fluorescence, bright yellow cut fluorescence, heavy asphaltic oil, 2" nubbin of Shale: dark gray, finely micaceous, with floating rounded sand grains at top.
8122.0-8133.0' (11.0')	Sandstone: gray to brown, medium to coarse grained, angular, subangular, medium sorted, medium porosity, trace of good porosity, white and black grains, trace of tripolitic chert grains, brown oil stain, gold sample fluorescence, bright yellow cut fluorescence; horizontal bedding with crossbedding, rare silty streaks; Shale (8127-8128'): light gray to gray, slightly micaceous, conchoidal fracture.
8133.0-8138.0' (5.0')	Sandstone: brown-gray, fine, medium, and coarse grained, slightly conglomeratic, angular, subangular, medium sorted, slight to medium porosity, poor oil stain, no sample fluorescence, bright yellow cut fluorescence, slightly crossbedded.
8138.0-8139.5' (1.5')	Sandstone: light gray to brown, fine grained, subangular, well sorted, slight porosity to medium porosity, poor oil stain, no sample fluorescence, bright yellow cut fluorescence; white grains common.
8139.5-8140	No sample. Made 0.5' on clean-out for Drill-Stem Test No. 1.
8140 - 8200	<u>Core No. 10, Cut 60', Recovered 59'</u>
8140.0-8182.0' (42.0')	Sandstone: light gray, gray to brown, very fine to fine grained, trace of medium grained, angular to subangular, well sorted, slight to medium porosity, trace of siliceous cement in part, rare, faint argillaceous partings; poor oil stain; rare, black, dead oil; rare,

asphaltic oil; white grains common; scattered black coal-like grains; shiny, conchoidal fracture; none to faint gold sample fluorescence; bright yellow cut fluorescence.

8182.0-8199.0' Sandstone: gray to light gray, very fine grained, silty, subangular, well sorted, slight to very slight porosity, trace of argillaceous partings; rare, black coal-like grains and pebbles; conglomeratic zone from 8193-8194' consisting of coal-like pebbles; faint oil stain, no sample fluorescence, bright yellow cut fluorescence.

8199.0-8200.0' No recovery.  
 (1.0')

8200 - 8270 Sandstone: light gray, gray to brown, very fine grained; becoming silty, subangular, well sorted, slight to medium porosity, faint oil stain, dead oil; zones from 8220-8240' and 8255-8270' with black coal-like, very coarse grains and possible pebbles; no sample fluorescence, bright yellow cut fluorescence; interbedded Shale: dark gray, splintery, partly with brown cast.

8270 - 8297 Shale: gray, finely micaceous, trace of splintery shale; trace of Siltstone: gray to brown.

8297 - 8317 Sandstone: light brown, very fine grained, subangular, well sorted, friable, slight to medium porosity, scattered light green glauconite; oil stained; gold sample fluorescence, bright yellow cut fluorescence; becoming predominantly a chert conglomerate at 8302'; composed of blue to gray, white and light green, translucent chert pebbles; trace of opaque chert pebbles, mostly angular, broken grains and pebbles.

8317 - 8345 Core No. 11, Cut 28', Recovered 24.9'

8317.0-8335.0' Limestone (with imbedded top inch of chert conglomerate, with dark gray pebbles): medium brown, fine crystalline, partly coarse crystalline, rare pelletoid, trace of light green glauconite, slightly sandy, scattered pebbles, very slightly dolomitic; oil stain; faint gold sample fluorescence, bright yellow cut fluorescence, streaming

- 8502 - 8508 Chert: very light blue to gray, translucent, very coarse grained, angular; very rare, rounded edges; probable pebble conglomerate(?)
- 8508 - 8515 Limestone: white, brown; trace of very dark fine pelletoid; sandy, spotty heavy oil; bleeding oil; no sample fluorescence, bright yellow cut fluorescence, streaming cut.
- 8515 - 8543.5 Core No. 12, Cut 28.5', Recovered 28.1'
- 8515.0-8520.0' Sandstone: brown, fine to medium grained, angular, medium sorted, very calcareous, dead oil stain, bleeding very heavy black asphaltic oil, chert grains common, no sample fluorescence, bright yellow cut fluorescence.  
(5.0')
- 8520.0-8533.0' Limestone: brown to light brown, fine pelletoid, very sandy to slightly sandy, in part crinoidal, trace of sparry calcite, dead to black asphaltic oil stain; bleeding oil on fractures and bedding planes.  
(13.0')
- 8533.0-8536.0' Limestone: medium gray to gray, fine to medium pelletoid, very sandy, sparry calcite; bottom foot with scattered quartzite and metamorphic pebbles.  
(3.0')
- 8536.0-8543.1' Claystone: medium gray to green, spotted red in top foot; grading to Claystone: brick red, slightly sandy; conchoidal fracture.  
(7.1')
- 8543.1-8543.5' No recovery.  
(0.4')
- 8543.5 - 8547 Claystone: red, green, shaly.
- 8547 - 8564 Sandstone: gray, brown, very fine grained, subangular, well sorted, slightly porous, dead and heavy asphaltic oil stain, calcareous to very calcareous, none to faint gold sample fluorescence, bright yellow cut fluorescence with Chert conglomerate (8552-8556'): light blue to gray; Limestone (8556-8558'): white to light brown, crystalline, trace of pelletoid; sandy; slight bleeding of heavy oil.
- 8564 - 8571 Shale: red.

- 8571 - 8578 Chert conglomerate: blue-gray, white, trace of black; loose, angular, broken pebbles.
- 8578 - 8585 Shale: red.
- 8585 - 8618 Limestone: white, light brown, pink, crystalline, slightly pelletoid, rare indistinct fossils, sandy, dark bleeding oil; shale partings.
- 8618 - 8633 Sandstone: gray, very fine grained, silty, angular, well sorted, scattered black dead oil, no sample fluorescence, dull yellow cut fluorescence.
- 8633 - 8657 Chert conglomerate:: white to gray, very coarse pebbles, rounded edges with dead oil; trace of black chert.
- 8657 - 8664 Shale: red, gray; trace of green shale.
- 8664 - 8677 Chert conglomerate: opaque white and translucent blue to gray; trace of black; trace of black dead oil residue and stain.
- 8677 - 8698 Shale: red, gray, green.
- 8698 - 8747 Interbedded Limestone, Shale and Sandstone, with Limestone: white, light brown, crystalline, slightly pelletoid, sandy, sparry calcite, brown stain, bleeding very heavy oil; Shale: red, gray, green; Sandstone: gray, very fine grained, subangular, well sorted, spotted with dead and very heavy oil; trace of coal-like grains; black, shiny, conchoidal fracture; no sample fluorescence, bright yellow cut fluorescence; trace of chert pebbles.
- 8747 - 8762 Chert conglomerate: blue to gray, trace of black, rare green, rare rounded pebbles, with trace of dead oil residue.
- 8762 - 8774 Shale: red, trace of light green, rare silt and limestone streaks.
- 8774 - 8786 Sandstone: light green, very fine grained, very silty, tight; trace with dead oil; interbedded Shale: red.
- 8786 - 8814 Interbedded Limestone and Shale, with Limestone: gray-brown, crystalline, sandy; trace of pelletoidal; rare glauconite, spotted heavy black asphaltic oil, faint gold sample fluorescence, bright yellow cut fluorescence; Shale: red.

- 8814 - 8824 Sandstone: light green, very fine grained, very silty, grading to sandy siltstone, very slightly dolomitic, tight.
- 8824 - 8876 Interbedded Shale, Limestone and Sandstone, with Shale: red; Limestone: white to gray, very heavy asphaltic oil, no sample fluorescence, bright yellow cut fluorescence; Sandstone: gray to brown, fine grained, angular, well sorted, friable, dead oil and trace of spotty black heavy oil.
- 8876 - 8883 Sandstone: light green, green and white to cream; very fine grained, angular, subangular, well sorted, trace of orange grains, silty, tight, slightly siliceous.
- 8883 - 8887 Sandstone: gray, very fine to fine grained, angular, subangular, friable, trace of dead oil and spotty, heavy black oil; no sample fluorescence, bright yellow cut fluorescence; trace of Limestone: white, gray, and brown crystalline, slightly pelletoidal, sandy, spotty, very heavy black asphaltic oil, no sample fluorescence, bright yellow cut fluorescence.
- 8887 - 8898 Chert conglomerate: light gray, green, and white, rare black, broken angular grains; trace of very coarse rounded pebbles, with rare black dead oil residue.
- 8898 - 8923 Sandstone: green to very light gray, and light orange, very fine to fine grained, silty, argillaceous; trace of orange grains.
- 8923 - 8934 Shale: red; trace of Limestone: pink, mottled, argillaceous, sandy.
- 8934 - 8992 Sandstone: pink to red, fine grained, trace of medium grained, angular, calcareous, varicolored grains; scattered rare chert pebbles; interbedded Shale: red, green.
- 8992 - 9000 Shale: red to maroon, trace of green shale, trace of sandy shale.
- 9000 - 9025 Sandstone: pink to red, very fine to fine grained, angular, well sorted, very calcareous; trace of calcareous veining, trace of glauconite; rare medium and coarse grains.
- 9025 - 9055 Sandstone: pink, green, very fine to coarse grained, subangular, subrounded, poorly sorted, slightly calcareous; trace of loose grains; trace of chert and varicolored grains; trace of interbedded Shale: red.

- 9055 - 9077 Chert conglomerate: varicolored grains and pebbles; trace of pink sandstone matrix; trace of varicolored limestone pebbles.
- 9077 - 9092 Shale: red-maroon, occasionally spotted green, trace of Siltstone: pink, calcareous.
- 9092 - 9165 Chert conglomerate: varicolored grains and pebbles; trace of pink sandstone matrix; trace of varicolored limestone pebbles; interbedded Shale: red-maroon, trace of green; Sandstone (9135-9140'): pink, varicolored, fine to coarse grained, slightly conglomeratic, with chert, limestone, shale, and quartz grains; sparry calcite; possible bedded Limestone (9144-9146'): light brown, dense.
- 9165 - 9188 Shale: maroon, trace of green; trace of light green-gray, clayey, soft; trace of conglomerate with chert, limestone and varicolored pebbles, angular, rarely subrounded.
- 9188 - 9226 Shale: light green, purple, yellow, mottled in part, micromicaceous, trace with micaceous sheen.
- 9226 - 9240 Chert conglomerate: varicolored, angular, coarse to very coarse grained, trace of pebbles, rounded; interbedded Shale: maroon.
- 9240 - 9246 Sandstone: pink to red, trace of green, mottled, very fine grained, trace of medium grained, silty, calcareous to very calcareous.
- 9246 - 9250 Shale: green, purple, varicolored, micromicaceous, with micaceous sheen.
- 9250 - 9256 Chert conglomerate: varicolored grains; trace of pebbles; trace of limestone pebbles.
- 9256 - 9276 Shale: green, purple, partly mottled, micromicaceous.
- 9276 - 9357 Shale: very dark gray-black, partly dark steel-blue to gray, micromicaceous, micaceous sheen; trace of Siltstone: dark gray, very rare calcite and quartz veining, tight; quartz veining becoming common; very rare schistose shale at 9320'; rare, very finely disseminated pyrite.
- 9357 - 9367 Core No. 13, Cut 10', Recovered 8.8'
- 9357.0-9365.8' (8.8') Argillite: very dark gray to black, micromicaceous, micaceous sheen, trace of slickensides; quartz veining common

in irregular and wavy stringers; trace of calcite veining; rare vertical fractures; low angle fractures fairly common; rare scattered very finely disseminated pyrite; wavy, shaly bedding; incipient schistosity.

9365.8-9367.0' No recovery.

## Discussion:

A series of sands with a well developed SP from 2700 to 4100' appear wet with porosities in the 30-33% range. Resistivities range from 1.5 to 3.0 ohm-meters. There is some evidence of invasion in these sands.

Discussion:

Porosities in the Lisburne Limestone range from 6% to 13% based on CNL/FDC cross plots and well confirmed by BHC porosities. Some faint evidence of possible fracturing can be seen.

Mr. S. L. Hewitt  
Husky Oil/NPR Operations, Inc.  
2525 C Street  
Anchorage, Ak 99503

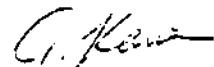

Dear Mr. Hewitt:

Dresser-Atlas began their first logging job on an NPRA well at J. W. Dalton No. 1 on May 28, 1979. The pipe was out of the hole at 1930 hours but the D-A crew found a damaged spot on their cable which should have been caught during their previous checks of the preceding two days. Repairs were made and the DIL began at 2130, but due to an SP drift it was necessary to re-log from 4200 to casing. Log was completed at 0400, May 29. CNL/TDC, RHC, HBD, Velocity Survey and sidewall cores followed, and while all logs were of very good quality, in my opinion the elapsed time was excessive for a comparatively shallow well; 32.5 hours. For instance the dipmeter required 6 hours of logging time and it took over 4 hours to run one sidewall core gun shooting 18 shots. Four hours elapsed before field prints were delivered. Mr. Tony Lawrence, Dresser's log analyst, was most cooperative and eager to please, but seemed uncertain in regard to certain tool characteristics and was somewhat evasive in responding to other questions.

Correlative log tops were: Tokok at 4714 as compared to 4385 in the W. T. Foran well and Pebble Shale at 7483, 7335 in Foran and 6700 in Drew Point. Correlation was good with both Foran and Drew Point.

A series of sands from 2700 to 4100 exhibit well developed SP characteristics in the order of 40 to 70 millivolts and appear to be fairly permeable since the DIL indicates some invasion has taken place. However, due to low resistivity values in the range of 1.5 to 3.0 ohmmeters all these sands appear to be water bearing. Salinity from SP computations is about 25,000 PPM. While the porosities of 30-33% appear high they are confirmed by all three porosity logs. An unusually high level of gamma radiation is seen in this well with the shale line being in the order of 80 to 100 API Units as contrasted with the usual 50 to 70 API Units in other wells. No zones of interest were found.

Very truly yours,

A. Kane

JULY 9, 1979

Mr. S. L. Hewitt  
Husky Oil/NPR Operations, Inc.  
2525 C Street  
Anchorage, Ak 99503

Dear Mr. Hewitt:

Dresser-Atlas began the final logging run on J. W. Dalton #1 at 2300 hours on June 27, 1979, and by 0230 hours on June 30 had completed two temperature logs, DIL, CBL/FDC, BHC, HED, Birdwell Velocity Survey and sidewall cores. Temperature tool failure occurred on the first run and necessitated re-logging from casing to TD. A drifting SP problem was encountered on the DIL and the log was run five times without good SP repeatability although the resistivity curves and the gamma ray repeated splendidly. The log required about 8 hours to run. On the CBL/FDC the neutron tool failed so the log was re-run twice. The BHC was satisfactory but the HED exhibited a very erratic deviation curve due to hole conditions and in some intervals the correlation curves were dead. The dipmeter is therefor of little use. 21 of 24 sidewall cores were recovered. Dresser had five personnel at the well and their attitude and co-operation were above reproach but in my opinion an average of over 6 hours per log at 9500 feet is excessive logging time. The same excessive logging time was experienced on the previous run when it took 32.5 hours to complete 6 logs at only 7500 feet. Most of the personnel were inexperienced in North Slope operations and appeared a bit unsure of themselves. The logs, as finally obtained were of good quality with the exception of the dipmeter.

Log formation tops were: Sag River, 7635; Shuhlik, 7756; Sadlerochit, 7893; Kavik, 8230; Lisburne, 8317 and Argillite at 9270. The Kingak could not be definitely placed.

Two zones are seen on the logs: 7970-7990 and 8080-8170 which are of interest, the upper zone averaging 17% porosity and water saturation ranging from 57% to 86%, the lower zone averaging 11% porosity and water saturation from 73% to 100%. Neither of these zones would probably result in commercial production but are certainly worthy of a test. The Lisburne exhibited good porosities ranging from 6% to 13% and extremely high resistivities in excess of 2000 ohm-meters. These high resistivity values repeated on 5 runs and so must be considered valid. The  $S_w$  values on the attached tabulation were computed using  $R_w = 0.15$  which was confirmed by both SP and  $R_{wa}$  calculations and thus can be used with confidence.

Very truly yours,

A. Kane

Final flow opened	6 hrs	Mud Pit Sample	- g - ppm - ppm
Final shut-in period	13 hrs. 15 min	Mud Pit Sample Filtrate	0.37 g 68 ppm 1650 ppm
Unseated packer at	1947 hrs 7-20-79 hrs	Mud Weight	10.1 g 17 ppm
		774 Sample	0.91 g 64°F. 1200 ppm

Description of initial flow period Very weak blow increasing to weak blow. At shut in well bubbling in 3" water from bubble hose.

Description of final flow period Opened with moderate blow continuing to strong blow at 4 hrs. Moderate to strong blow remainder of open period. No gas to surface. At strongest point would bubble rapidly at the bottom of bubble bucket.

## LABORATORY REPORT

RECEIVING NO.	DATE REC'D
SAMPLE DESCRIPTION	
Core sample from USGS/Husky N.P.R.	
J.W. Dalton Well # 1 at 7515' (Sidewall core, analyzed from GR shale, courtesy RECEIVED FROM Dresser-Atlas)	
W.H. Fertl	
OBJECT OF TEST	
Mineralogy	

Analysis by x-ray diffraction gave the following components:

### 7515 Feet

20-25% Mica  
25-30% Chlorite  
10-15% Feldspar  
2-5 % Dolomite  
5-10% Pyrite  
10-15% Quartz
